Auditory system - Wikipedia

The cortical system outlined here appears to apply broadly to anthropoid primates (monkeys, apes, and humans), and at least partly to prosimian primates. The human auditory system obviously has cortical specializations for language, and the cortical systems in the two hemispheres are not completely symmetrical.

The auditory system is a body system that is responsible for the sense of hearing. It is divided into two subsystems- the peripheral auditory system (outer ear, middle ear and inner ear) and the central auditory system (from the cochlear nucleus up to the primary auditory cortex).

Auditory scene analysis involves identifying the content ("what") and the location ("where") of sounds in the environment. Evidence from anatomical and neurophysiological studies in non-human primates (1-5) suggests that identification and localization of auditory events may be functionally segregated in specialized auditory streams.. Combining anatomical and electrophysiological ...

Localization and the Human Auditory System. Localization refers to the brain's ability to determine the 3D location of sound in the real world. Despite only having two ears, we're able to deduce the 3D position of the sounds around us. Humans rely on audio cues such as timing, ...

The human auditory field (green) is limited by the threshold curve (bottom) and a curve giving the upper limit of sound perception (top). At each frequency, between 20 Hz and 20 kHz, the threshold of our sensitivity is different. The best threshold (at around 2 kHz) is close to 0 dB.

Human ear - Human ear - Analysis of sound by the auditory nervous system: Evidence of orderly spatial representations of the organ of Corti at the lower levels of the auditory pathway has been reported by many investigators. These patterns seem to be in accord with the place theory of the cochlear analysis of sound. Physiological evidence of tuning of the auditory system also has been obtained ...

Human ear - Analysis of sound by the auditory nervous system

mary functions of the auditory system is to convert the acoustic energy produced by the talker—human speech sounds—into neural energy that can be deciphered by the brain of the listener. This process is the central topic of this chapter. This chapter is divided into three main sections.

Structure and Function of the Auditory System

This review traces the structural maturation of the human auditory system, and compares the timeline of anatomical development with cotemporaneous physiological and behavioral events. During the embryonic period, there is formation of basic structure at all levels of the system, i.e. the inner ear, ...

The Human Auditory System: A Timeline of Development

Abstract. How the human auditory system extracts perceptually relevant acoustic features of speech is unknown. To address this question, we used intracranial recordings from nonprimary auditory cortex in the human superior temporal gyrus to determine what acoustic information in speech sounds can be reconstructed from population neural activity.

Studying the human subcortical auditory system non-invasively is challenging due to its small, densely packed structures deep within the brain. Additionally, the elaborate three-dimensional (3-D) structure of the system can be difficult to understand based on currently available 2-D schematics and animal models.
